Water pricing policies are crucial tools within management plans with the primary goal of stimulating users to a more sustainable consumption and of mitigating inefficiencies. We propose a reform of the methodology by which fees for the use of public waters is defined, with reference to the case study of the Piedmont region. The objective is not only to recover the cost of measures implemented to protect water resources, but to foster an efficient allocation among competing uses and the sharing of responsibility among users to achieve adequate water quality status.
